

Secure Cryptographic Protocol Execution based on Runtime Verification

Secure Communication in the Quantum Era (SPS G5448)
February 5th, 2020

Christian Colombo
Mark Vella

Cryptographic Protocols

Design

Proofs to validate design against threat models

Implementation

Difficult to make it fully secure...

So many things can go wrong!

Levels of abstraction of security threats

(High level) Wrong protocol
implementation

The protocol implementation might deviate from
the verified (theoretical) design

Medium level threats

Malware, Data leaks, etc

Low level threats

Arithmetic overflows, undefined downcasts,
and invalid pointer references

Hardware

Can hardware be trusted?
Side Channel attacks?

L-Università
ta' Malta

It is difficult to make implementation fully secure...
but we can raise the bar as much as possible.

Our strategy

Isolate!

Our strategy

Isolate!

Monitor!

L-Università
ta' Malta

**Monitor code while executing
(High level)**

Preliminary case study

Preliminary implementation

Setup using Binary-level instrumentation

L-Università
ta' Malta

Preliminary implementation

Setup using Binary-level instrumentation

Through which monitors can gain visibility

Properties verified (High level) on ECDHE

Digital certificate verification is done (in order to authenticate public keys sent by peers)

Properties verified (High level) on ECDHE

Validation of remote peer's public key on each exchange is done (unless the session is aborted)

Properties verified (High level) on ECDHE

Once master secret is established, private keys should be **scrubbed from memory** (to limit the impact of memory leak attacks such as Heartbleed, irrespective of whether the session is aborted)

Feasibility study of approach

Is the approach possible for a realistic code base?

Is the approach feasible in terms of overheads?

Used the Firefox case study on top 100 Alexa sites

Feasibility study

```
/* TID 0x1003 */
200 ms 0x1003 PR_Close()
200 ms 0x1003 fd:0x7faa3ded6e20
/* TID 0xffb */
312 ms 0xffb SSL_ImportFD()
312 ms 0xffb ret:0x7faa43591940
312 ms 0xffb SSL_AuthCertificateHook()
312 ms 0xffb fd:0x7faa43591940
312 ms 0xffb ret:0x0
312 ms 0xffb PR_Connect()
312 ms 0xffb fd:0x7faa43591940
531 ms 0xffb SECKEY_CreateECPrivateKey()
531 ms 0xffb cx:0x7faa3deda988
532 ms | 0xffb EC_ValidatePublicKey()
532 ms | 0xffb ret:0x0
532 ms 0xffb ret:0x7faa3dd66020::7faa3dd66020 c0 fe d9
3d ...=
533 ms 0xffb SECKEY_CreateECPrivateKey()
533 ms 0xffb cx:0x7faa3deda988
534 ms | 0xffb EC_ValidatePublicKey()
539 ms | 0xffb ret:0x0
539 ms 0xffb ret:0x7faa3dd68020::7faa3dd68020 00 f1 10
```

Overheads measurement

Configuration	Pages	Page load time (ms)	
		<i>mean</i>	<i>std. dev.</i>
<i>No RV</i>	1,000	6,918.37	24,870.86
<i>With RV</i>	1,000	7,282.35	27,328.9
<i>Mean overhead</i>		0.05	
<i>Wilcoxon signed-rank test</i>		p=0.281	

Overheads measurement

Configuration	Pages	Page load <i>mean</i>	std. dev.
<i>No RV</i>	1,000	6,918.37	24,870.86
<i>With RV</i>	1,000	7,282.35	27,328.9
<i>Mean overhead</i>		0.05	
<i>Wilcoxon signed-rank test</i>		p=0.281	

0.05 ms per page

Lessons learnt

Good start with promising results - approach seems feasible

Beware:

Program comprehension is required, both for setting up function hooks as well as to enable individual TLS session monitoring

Real-world code tends to be written in a manner to **favor efficient execution rather than monitorability** (eg, was difficult to keep track of particular sessions on the server)
