Chapter 5

Chunking

5.1 Introduction

Chunking is an efficient and robust method for identifying short phrases in text, or “chunks”. Chunks are non-overlapping spans of text, usually consisting of a head word (such as a noun) and the adjacent modifiers and function words (such as adjectives and determiners). For example, here is some Wall Street Journal text with noun phrase chunks marked using brackets (this data is distributed with NLTK):

[ The/DT market/NN ] for/IN [ system-management/NN software/NN ] for/IN [ Digital/NNP ] [ 's/POS hardware/NN ] is/VBZ fragmented/JJ enough/RB that/IN [ a/DT giant/NN ] such/JJ as/IN [ Computer/NNP Associates/NNPS ] should/MD do/VB well/RB there/RB ./.

There are two motivations for chunking: to locate information, and to ignore information. In the former case, we may want to extract all noun phrases so they can be indexed. A text retrieval system could use such an index to support efficient retrieval for queries involving terminological expressions.

The reverse side of the coin is to ignore information. Suppose that we want to study syntactic patterns, finding particular verbs in a corpus and displaying their arguments. For instance, here are some uses of the verb gave in the Wall Street Journal (in the Penn Treebank corpus sample). After doing NP-chunking, the internal details of each noun phrase have been suppressed, allowing us to see some higher-level patterns:

| gave NP |
| gave up NP in NP |
| gave NP up |
| gave NP NP |
| gave NP to NP |

In this way we can acquire information about the complementation patterns of a verb like gave, for use in the development of a grammar (see Chapter 7).

Chunking in NLTK begins with tagged text, represented as a flat tree:

```python
>>> from nltk_lite import chunk
>>> tagged_text = "the/DT little/JJ cat/NN sat/VBD on/IN the/DT mat/NN"
>>> input = chunk.tagstr2tree(tagged_text)
>>> input.draw()
```
5.2 Defining and Representing Chunks

5.2.1 An Analogy

Two of the most common operations in language processing are segmentation and labeling. Recall that in tokenization, we segment a sequence of characters into tokens, while in tagging we label each of these tokens. Moreover, these two operations of segmentation and labeling go hand in hand. We break up a stream of characters into linguistically meaningful segments (e.g. words) so that we can classify those segments with their part-of-speech categories. The result of such classification is represented by adding a label to the segment in question.

In this chapter we do this segmentation and labeling at a higher level, as illustrated in Figure 5.1. The solid boxes show word-level segmentation and labeling, while the dashed boxes show a higher-level segmentation and labeling. These larger pieces are called chunks, and the process of identifying them is called chunking.

Like tokenization, chunking can skip over material in the input. Tokenization omits white space and punctuation characters. Chunking uses only a subset of the tokens and leaves others out.
5.2.2 Chunking vs Parsing

Chunking is akin to parsing in the sense that it can be used to build hierarchical structure over text. There are several important differences, however. First, as noted above, chunking is not exhaustive, and typically omits items in the surface string. Second, where parsing constructs deeply nested structures, chunking creates structures of fixed depth, (typically depth 2). These chunks often correspond to the lowest level of grouping identified in the full parse tree, as illustrated in the parsing and chunking examples in (1) below:

(1a)

A significant motivation for chunking is its robustness and efficiency relative to parsing. Parsing uses recursive phrase structure grammars and arbitrary-depth trees. Parsing has problems with robustness, given the difficulty in getting broad coverage and in resolving ambiguity. Parsing is also relatively inefficient: the time taken to parse a sentence grows with the cube of the length of the sentence, while the time taken to chunk a sentence only grows linearly.

5.2.3 Representing Chunks: Tags vs Trees

As befits its intermediate status between tagging and parsing, chunk structures can be represented using either tags or trees. The most widespread file representation uses so-called IOB tags. In this scheme, each token is tagged with one of three special chunk tags, I (inside), O (outside), or B (begin). A token is tagged as B if it marks the beginning of a chunk. Subsequent tokens within the chunk are tagged I. All other tokens are tagged O. The B and I tags are suffixed with the chunk type, e.g. B-NP, I-NP. Of course, it is not necessary to specify a chunk type for tokens that appear outside a chunk, so these are just labeled O. An example of this scheme is shown in Figure 5.2.

![Figure 5.2: Tag Representation of Chunk Structures](image)

IOB tags have become the standard way to represent chunk structures in files, and we will also be using this format. Here is an example of the file representation of the information in Figure 5.2:
5.3. Chunking

In this representation, there is one token per line, each with its part-of-speech tag and its chunk tag. We will see later that this format permits us to represent more than one chunk type, so long as the chunks do not overlap. This file format was developed as part of the chunking evaluation task run by the Conference on Natural Language Learning in 2000, and has come to be called the IOB Format. A section of Wall Street Journal text has been annotated in this format.

As we saw earlier, chunk structures can also be represented using trees. These have the benefit that each chunk is a constituent that can be manipulated directly. An example is shown in Figure 5.3:

![Figure 5.3: Tree Representation of Chunk Structures](image)

NLTK uses trees for its internal representation of chunks, and provides methods for reading and writing such trees to the IOB format. By now you should understand what chunks are, and how they are represented. In the next section you will see how to build a simple chunker.

5.3 Chunking

A chunker finds contiguous, non-overlapping spans of related tokens and groups them together into chunks. Chunkers often operate on tagged texts, and use the tags to make chunking decisions. In this section we will see how to write a special type of regular expression over part-of-speech tags, and then how to combine these into a chunk grammar. Then we will set up a chunker to chunk some tagged text according to the grammar.

5.3.1 Tag Patterns

A tag pattern is a sequence of part-of-speech tags delimited using angle brackets, e.g. `<DT><JJ><NN>`. Tag patterns are the same as the regular expression patterns we have already seen, except for two differences which make them easier to use for chunking. First, angle brackets group their contents into atomic units, so “<NN>+” matches one or more repetitions of the tag NN; and “<NN|JJ>” matches the NN or JJ. Second, the period wildcard operator is constrained not to cross tag delimiters, so that “<N.*” matches any single tag starting with N.

Now, consider the following noun phrases from the Wall Street Journal:

- another/DT sharp/JJ dive/NN
- trade/NN figures/NNS
- any/DT new/JJ policy/NN measures/NNS
earlier/JJR stages/NNS  
Panamanian/JJ dictator/NN Manuel/NNP Noriega/NNP

We can match these using a slight refinement of the first tag pattern above: `<DT>?<JJ.*>*<NN.*>+. This can be used to chunk any sequence of tokens beginning with an optional determiner DT, followed by zero or more adjectives of any type JJ.* (including relative adjectives like earlier/JJR), followed by one or more nouns of any type NN.*. It is easy to find many more difficult examples:

- his/PRP$ Mansion/NNP House/NNP speech/NN
- the/DT price/NN cutting/VBG
- 3/CD %/NN to/TO 4/CD %/NN
- more/JJR than/IN 10/CD %/NN
- the/DT fastest/JJS developing/VBG trends/NNS
- ’s/POS skill/NN

Your challenge will be to come up with tag patterns to cover these and other examples.

### 5.3.2 Chunking with Regular Expressions

The chunker begins with a flat structure in which no tokens are chunked. Patterns are applied in turn, successively updating the chunk structure. Once all of the patterns have been applied, the resulting chunk structure is returned. Here is a simple chunk grammar consisting of two patterns. The first pattern matches an optional determiner, zero or more adjectives, then a noun. We also define some input to be chunked.

```python
>>> grammar = r""
... NP:
... {<DT>?<JJ>*<NN>} # chunk determiners, adjectives and nouns
... {<NNP>++} # chunk sequences of proper nouns
... ""
>>> tagged_text = "the/DT little/JJ cat/NN sat/VBD on/IN the/DT mat/NN"
>>> input = chunk.tagstr2tree(tagged_text)
```

Next we can set up a chunker and run it on the input:

```python
>>> cp = chunk.Regexp(grammar)
>>> print cp.parse(input)
(S: (NP: ('the', 'DT') ('little', 'JJ') ('cat', 'NN')) ('sat', 'VBD') ('on', 'IN') (NP: ('the', 'DT') ('mat', 'NN')))
```

If a tag pattern matches at multiple overlapping locations, the first match takes precedence. For example, if we apply a rule that matches two consecutive nouns to a text containing three consecutive nouns, then the first two nouns will be chunked:

```python
>>> nouns = chunk.tagstr2tree("money/NN market/NN fund/NN")
>>> grammar = "NP: {<NN><NN>} # Chunk two consecutive nouns"
>>> cp = chunk.Regexp(grammar)
>>> print cp.parse(nouns)
(S: (NP: ('money', 'NN') ('market', 'NN')) ('fund', 'NN'))
```
5.3.3 Developing Chunkers

Creating a good chunker usually requires several rounds of development and testing, during which existing rules are refined and new rules are added. In order to diagnose any problems, it often helps to trace the execution of a chunker, using its `trace` argument. The tracing output shows the rules that are applied, and uses braces to show the chunks that are created at each stage of processing. In the following example, two chunk patterns are applied to the input sentence. The first rule finds all sequences of three tokens whose tags are `DT`, `JJ`, and `NN`, and the second rule finds any sequence of tokens whose tags are either `DT` or `NN`.

```python
>>> grammar = r""
... NP:
...  {<DT><JJ><NN>}  # Chunk det+adj+noun
...  {<DT|NN>+}     # Chunk sequences of NN and DT
... ""

>>> cp = chunk.Regexp(grammar)

>>> print cp.parse(input, trace=1)
# Input:
<DT> <JJ> <NN> <VBD> <IN> <DT> <NN>
# Chunk det+adj+noun:
{<DT> <JJ> <NN>} <VBD> <IN> <DT> <NN>
# Chunk sequences of NN and DT:
{<DT> <JJ> <NN>} <VBD> <IN> {<DT> <NN>}
(S:
  (NP: ('the', 'DT') ('little', 'JJ') ('cat', 'NN'))
  ('sat', 'VBD')
  ('on', 'IN')
  (NP: ('the', 'DT') ('mat', 'NN')))
```

Observe that when we chunk material that is already partially chunked, the chunker will only create chunks that do not partially overlap existing chunks. Thus, if we apply these two rules in reverse order, we will get a different result:

```python
>>> grammar = r""
... NP:
...  {<DT|NN>+}     # Chunk sequences of NN and DT
...  {<DT><JJ><NN>}  # Chunk det+adj+noun
... ""

>>> cp = chunk.Regexp(grammar)

>>> print cp.parse(input, trace=1)
# Input:
<DT> <JJ> <NN> <VBD> <IN> <DT> <NN>
# Chunk sequences of NN and DT:
{<DT>} <JJ> <NN>} <VBD> <IN> {<DT> <NN>}
# Chunk det+adj+noun:
{<DT>} <JJ> <NN>} <VBD> <IN> {<DT> <NN>}
(S:
  (NP: ('the', 'DT'))
  ('little', 'JJ')
  (NP: ('cat', 'NN'))
  ('sat', 'VBD')
  ('on', 'IN')
  (NP: ('the', 'DT') ('mat', 'NN')))
```
5.3.4 Exercises

1. **Chunking Demonstration:** Run the chunking demonstration:

   ```python
   from nltk_lite.parse import chunk
   chunk.demo()  # the chunker
   ```

2. **IOB Tags:** The IOB format categorizes tagged tokens as I, O and B. Why are three tags necessary? What problem would be caused if we used I and O tags exclusively?

3. Write a tag pattern to match noun phrases containing plural head nouns, e.g. “many/JJ researchers/NNS”, “two/CD weeks/NNS”, “both/DT new/JJ positions/NNS”. Try to do this by generalizing the tag pattern that handled singular noun phrases.

4. Write tag pattern to cover noun phrases that contain gerunds, e.g. “the/DT receiving/VBG end/NN”, “assistant/NN managing/VBG editor/NN”. Add these patterns to the grammar, one per line. Test your work using some tagged sentences of your own devising.

5. Write one or more tag patterns to handle coordinated noun phrases, e.g. “July/NNP and/CC August/NNP”, “all/DT your/PRP$ managers/NNS and/CC supervisors/NNS”, “company/NN courts/NNS and/CC adjudicators/NNS”.

6. Sometimes a word is incorrectly tagged, e.g. the head noun in “12/CD or/CC so/RB cases/VBZ”. Instead of requiring manual correction of tagger output, good chunkers are able to work with the erroneous output of taggers. Look for other examples of correctly chunked noun phrases with incorrect tags.

5.4 Scaling Up

Now that you have a taste of what chunking can do, you are ready to look at a chunked corpus, and use it in developing and testing more complex chunkers. We will begin by looking at the mechanics of converting IOB format into an NLTK tree, then at how this is done on a larger scale using the corpus directly. We will see how to use the corpus to score the accuracy of a chunker, then look some more flexible ways to manipulate chunks. Throughout our focus will be on scaling up the coverage of a chunker.

5.4.1 Reading IOB Format and the CoNLL 2000 Corpus

Using the `nltk_lite.corpora` module we can load Wall Street Journal text that has been tagged, then chunked using the IOB notation. The chunk categories provided in this corpus are NP, VP and PP. As we have seen, each sentence is represented using multiple lines, as shown below:

```
he PRP B-NP
accepted VBD B-VP
the DT B-NP
position NN I-NP
...
5.4. Scaling Up

A conversion function `chunk.conllstr2tree()` builds a tree representation from one of these multi-line strings. Moreover, it permits us to choose any subset of the three chunk types to use. The example below produces only NP chunks:

```python
>>> text = '''
... he PRP B-NP
... accepted VBD B-VP
... the DT B-NP
... position NN I-NP
... of IN B-PP
... vice NN B-NP
... chairman NN I-NP
... of IN B-PP
... Carlyle NNP B-NP
... Group NNP I-NP
... , , O
... a DT B-NP
... merchant NN I-NP
... banking NN I-NP
... concern NN I-NP
... . O
... '''

```chunk.conllstr2tree(text, chunk_types=('NP',)).draw()
```

We can use the NLTK corpus module to access a larger amount of chunked text. The CoNLL 2000 corpus contains 270k words of Wall Street Journal text, with part-of-speech tags and chunk tags in the IOB format. We can access this data using an NLTK corpus reader called `conll2000`. Here is an example:

```python
>>> from nltk_lite.corpora import conll2000, extract

>>> print extract(2000, conll2000.chunked())

(S:
 (NP: ('Health-care', 'JJ') ('companies', 'NNS'))
 (VP: ('should', 'MD') ('get', 'VB'))
 ('healthier', 'JJR')
 (PP: ('in', 'IN'))
 (NP: ('the', 'DT') ('third', 'JJ') ('quarter', 'NN'))
 ('.', '.'))
```

This just showed three chunk types, for NP, VP and PP. We can also select which chunk types to read:

```python
>>> from nltk_lite.corpora import conll2000, extract

>>> print extract(2000, conll2000.chunked(chunk_types=('NP',)))

(S:
 (NP: ('Health-care', 'JJ') ('companies', 'NNS'))
 ('should', 'MD')
 ('get', 'VB'))
```
5.4.2 Simple Evaluation and Baselines

Armed with a corpus, it is now possible to do some simple evaluation. The first evaluation is to establish a baseline for the case where nothing is chunked:

```python
>>> cp = chunk.Regexp(""
>>> print chunk.accuracy(cp, conll2000.chunked(chunk_types=('NP',)))
0.440845995079
```

Now let’s try a naive regular expression chunker that looks for tags beginning with letters that are typical of noun phrase tags:

```python
>>> grammar = r"""NP: {<\[CDJNP\].*>+}"""
>>> cp = chunk.Regexp(grammar)
>>> print chunk.accuracy(cp, conll2000.chunked(chunk_types=('NP',)))
0.874479872666
```

We can extend this approach, and create a function `chunked_tags()` that takes some chunked data, and sets up a conditional frequency distribution. For each tag, it counts up the number of times the tag occurs inside a chunk (the `True` case), or outside a chunk (the `False` case). It returns a list of those tags that occur inside chunks more often than outside chunks.

```python
def chunked_tags(train):
    ...
    """Generate a list of tags that tend to appear inside chunks"""
    ...
    from nltk_lite.probability import ConditionalFreqDist
    ...
    cfdist = ConditionalFreqDist()
    ...
    for t in train:
        ...
        for word, tag, chtag in chunk.tree2conlltags(t):
            ...
            if chtag == "O":
                ...
                cfdist[tag].inc(False)
            ...
            else:
                ...
                cfdist[tag].inc(True)
    ...
    return [tag for tag in cfdist.conditions() if cfdist[tag].max() == True]
```

The next step is to convert this list of tags into a tag pattern. To do this we need to “escape” all non-word characters, by preceding them with a backslash. Then we need to join them into a disjunction. This process would convert a list `['NN', 'NN$']` into the tag pattern `<NN|NN$>`. The following function does this work, and returns a regular expression chunker:

```python
def baseline_chunker(train):
    ...
    import re
    ...
    chunk_tags = [re.sub(r'(\W)', r'\\\1', tag) for tag in chunked_tags(train)]
    ...
    grammar = 'NP: {<\+ | >\+}.join(chunk_tags) + >+}'
    ...
    return chunk.Regexp(grammar)
```

The final step is to train this chunker and test its accuracy (this time on data not seen during training):

```python
>>> cp = baseline_chunker(conll2000.chunked(files='train', chunk_types=('NP',)))
>>> print chunk.accuracy(cp, conll2000.chunked(files='test', chunk_types=('NP',)))
0.914262194736
```
5.4.3 Splitting and Merging (incomplete)

[Notes: the above approach creates chunks that are too large, e.g. the cat the dog chased would be given a single NP chunk because it does not detect that determiners introduce new chunks. For this we would need a rule to split an NP chunk prior to any determiner, using a pattern like: "NP: <.*>{<DT>}". We can also merge chunks, e.g. "NP: <NN>{<NN}>".]

5.4.4 Chinking

Sometimes it is easier to define what we don’t want to include in a chunk than it is to define what we do want to include. In these cases, it may be easier to build a chunker using a method called chinking.

The word chink initially meant a sequence of stopwords, according to a 1975 paper by Ross and Tukey (cited by Abney in the recommended reading for this chapter). Following Abney, we define a chink is a sequence of tokens that is not included in a chunk. In the following example, sat/VBD on/IN is a chink:

[ the/DT little/JJ cat/NN ] sat/VBD on/IN [ the/DT mat/NN ]

Chinking is the process of removing a sequence of tokens from a chunk. If the sequence of tokens spans an entire chunk, then the whole chunk is removed; if the sequence of tokens appears in the middle of the chunk, these tokens are removed, leaving two chunks where there was only one before. If the sequence is at the beginning or end of the chunk, these tokens are removed, and a smaller chunk remains. These three possibilities are illustrated in the following table:

<table>
<thead>
<tr>
<th>Chinking</th>
<th>Entire chunk</th>
<th>Middle of a chunk</th>
<th>End of a chunk</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input</td>
<td>[a/DT big/JJ cat/NN]</td>
<td>[a/DT big/JJ cat/NN]</td>
<td>[a/DT big/JJ cat/NN]</td>
</tr>
<tr>
<td>Operation</td>
<td>Chink “DT JJ NN”</td>
<td>Chink “JJ”</td>
<td>Chink “DT”</td>
</tr>
<tr>
<td>Pattern</td>
<td>“)DT JJ NN(“</td>
<td>“)JJ{“</td>
<td>“)DT{“</td>
</tr>
<tr>
<td>Output</td>
<td>a/DT big/JJ cat/NN</td>
<td>[a/DT] big/JJ [cat/NN]</td>
<td>[a/DT big/JJ] cat/NN</td>
</tr>
</tbody>
</table>

Table 5.1:

In the following grammar, we put the entire sentence into a single chunk, then excise the chink:

```python
>>> grammar = r"\\n... NP: ... {<.*>}{<DT>} # Chunk everything ... )<VBD|IN>#{ # Chink sequences of VBD and IN ... """
>>> cp = chunk.Regexp(grammar)
>>> print cp.parse(input)
(S:
 (NP: (the, 'DT') (little, 'JJ') (cat, 'NN'))
 (sat, 'VBD')
 (on, 'IN')
 (NP: (the, 'DT') (mat, 'NN')))
```

A chunk grammar can use any number of chunking and chinking patterns in any order.

February 1, 2007

Bird, Klein & Loper
5.4.5 Multiple Chunk Types (incomplete)

So far we have only developed NP chunkers. However, as we saw earlier in the chapter, the CoNLL chunking data is also annotated for PP and VP chunks. Here is an example, to show the structure we get from the corpus and the flattened version that will be used as input to the parser.

```python
>>> example = extract(2000, conll2000.chunked())
>>> print example
(S:
  (NP: ('Health-care', 'JJ') ('companies', 'NNS'))
  (VP: ('should', 'MD') ('get', 'VB'))
  ('healthier', 'JJR')
  (PP: ('in', 'IN'))
  (NP: ('the', 'DT') ('third', 'JJ') ('quarter', 'NN'))
  (',', '.'))
```

Now we can set up a multi-stage chunk grammar. It will have one stage for each of the chunk types.

```python
>>> grammar = r""
... NP: {<DT>?<JJ>*<NN.*>+} # noun phrase chunks
... VP: {<TO>?<VB.*>} # verb phrase chunks
... PP: {<IN>} # prepositional phrase chunks
... ""
>>> cp = chunk.Regexp(grammar)
>>> print cp.parse(example.flatten(), trace=1)
# Input:
<JJ> <NNS> <MD> <VB> <JJR> <IN> <DT> <JJ> <NN> <.>
# noun phrase chunks:
{<JJ> <NNS>} <MD> <VB> <JJR> <IN> {<DT> <JJ> <NN>} <.>
# Input:
<NP> <MD> <VB> <JJR> <IN> <NP> <.>
# verb phrase chunks:
<NP> <MD> {<VB>} <JJR> <IN> <NP> <.>
# Input:
<NP> <MD> <VP> <JJR> <IN> <NP> <.>
# prepositional phrase chunks:
<NP> <MD> <VP> <JJR> {<IN>} <NP> <.>
(S:
  (NP: ('Health-care', 'JJ') ('companies', 'NNS'))
  ('should', 'MD')
  (VP: ('get', 'VB'))
  ('healthier', 'JJR'))
```

Bird, Klein & Loper

5.4. Scaling Up

(PP: (‘in’, ‘IN’))
(NP: (‘the’, ‘DT’) (‘third’, ‘JJ’) (‘quarter’, ‘NN’) (‘.’, ‘.’))

5.4.6 Exercises

1. Simple Chunker: Pick one of the three chunk types in the CoNLL corpus. Inspect the CoNLL corpus and try to observe any patterns in the POS tag sequences that make up this kind of chunk. Develop a simple chunker using the regular expression chunker `chunk`. Discuss any tag sequences that are difficult to chunk reliably.

2. Automatic Analysis: Pick one of the three chunk types in the CoNLL corpus. Write functions to do the following tasks for your chosen type:
   a) List all the tag sequences that occur with each instance of this chunk type.
   b) Count the frequency of each tag sequence, and produce a ranked list in order of decreasing frequency; each line should consist of an integer (the frequency) and the tag sequence.
   c) Inspect the high-frequency tag sequences. Use these as the basis for developing a better chunker.

3. Chinking: An early definition of `chunk` was the material that occurs between chinks. Develop a chunker which starts by putting the whole sentence in a single chunk, and then does the rest of its work solely by chinking. Determine which tags (or tag sequences) are most likely to make up chinks with the help of your own utility program. Compare the performance and simplicity of this approach relative to a chunker based entirely on chunk rules.

4. Complex Chunker: Develop a chunker for one of the chunk types in the CoNLL corpus using a regular-expression based chunk grammar `RegexpChunk`. Use any combination of rules for chunking, chinking, merging or splitting.

5. Inherent ambiguity: We saw in the tagging chapter that it is possible to establish an upper limit to tagging performance by looking for ambiguous n-grams, n-grams that are tagged in more than one possible way in the training data. Apply the same method to determine an upper limit on the performance of an n-gram chunker.

6. Baseline NP Chunker: The baseline chunker presented in the evaluation section tends to create larger chunks than it should. For example, the phrase: `[every/DT time/NN] [she/PRP] sees/VBZ [a/DT newspaper/NN]` contains two consecutive chunks, and our baseline chunker will incorrectly combine the first two: `[every/DT time/NN she/PRP]`. Write a program that finds which of these chunk-internal tags typically occur at the start of a chunk, then devise a `SplitRule` that will split up these chunks. Combine this rule with the existing baseline chunker and re-evaluate it, to see if you have discovered an improved baseline.

7. Predicate structure: Develop an NP chunker which converts POS-tagged text into a list of tuples, where each tuple consists of a verb followed by a sequence of noun phrases and prepositions, e.g. `the little cat sat on the mat` becomes `(‘sat’, ‘on’, ‘NP’) ...`
8. **Penn Treebank NP Chunking Format:** The Penn Treebank contains a section of tagged Wall Street Journal text which has been chunked into noun phrases. The format uses square brackets, and we have encountered it several times during this chapter. It can be accessed by importing the Treebank corpus reader (from nltk_lite.corpora import treebank), then iterating over its chunked items (for sent in treebank.chunked()). These items are flat trees, just as we got using conll2000.chunked().

   a) Consult the documentation for the NLTK chunk package to find out how to generate Treebank and IOB strings from a tree. Write functions chunk2brackets() and chunk2iob() which take a single chunk tree as their sole argument, and return the required multi-line string representation.

   b) Write command-line conversion utilities bracket2iob.py and iob2bracket.py that take a file in Treebank or CoNLL format (resp) and convert it to the other format. (Obtain some raw Treebank or CoNLL data from the NLTK Corpora, save it to a file, and then use open(filename).readlines() to access it from Python.)

5.5 N-Gram Chunking

Our approach to chunking has been to try to detect structure based on the part-of-speech tags. We have seen that the IOB format represents this extra structure using another kind of tag. The question arises then, as to whether we could use the same n-gram tagging methods we saw in the last chapter, applied to a different vocabulary.

The first step is to get the word,tag,chunk triples from the CoNLL corpus and map these to tag,chunk pairs:

```python
>>> from nltk_lite import tag
>>> chunk_data = [(t,c) for w,t,c in chunk.tree2conlltags(chtree)] ... for chtree in conll2000.chunked()]
```

5.5.1 A Unigram Chunker

Now we can train and score a unigram chunker on this data, just as if it was a tagger:

```python
>>> unigram_chunker = tag.Unigram()
>>> unigram_chunker.train(chunk_data)
>>> print tag.accuracy(unigram_chunker, chunk_data)
0.781378851068
```

This chunker does reasonably well. Let’s look at the errors it makes. Consider the opening phrase of the first sentence of the chunking data, here shown with part of speech tags:

```
Confidence/NN in/IN the/DT pound/NN is/VBZ widely/RB expected/VBN to/TO take/VB another/DT sharp/JJ dive/NN
```

We can try the unigram chunker out on this first sentence by creating some “tokens” using `[t for t,c in chunk_data[0]]`, then running our chunker over them using list(unigram_chunker.tag(tokens)). The unigram chunker only looks at the tags, and tries to add chunk tags. Here is what it comes up with:
5.6. Cascaded Chunkers

NN/I-NP IN/B-PP DT/B-NP NN/I-NP VBZ/B-VP RB/O VBN/I-VP TO/B-PP VB/I-VP
DT/B-NP JJ/I-NP NN/I-NP

Notice that it tags the first noun Confidence/NN incorrectly as I-NP and not B-NP, because nouns usually do not occur at the start of noun phrases in the training data. It correctly tags the second pound/NN as I-NP (this noun occurs after a determiner). It incorrectly tags widely/RB as outside O, and it incorrectly tags the infinitival to/TO as B-PP, as if it was a preposition starting a prepositional phrase.

5.5.2 A Bigram Chunker (incomplete)

[Why these problems might go away if we look at the previous chunk tag?]

Let’s run a bigram chunker:

```python
>>> bigram_chunker = tag.Bigram(backoff=unigram_chunker)
>>> bigram_chunker.train(chunk_data)
>>> print tag.accuracy(bigram_chunker, chunk_data)
0.89312652614
```

We can run the bigram chunker over the same sentence as before using `list(bigram_chunker.tag(tokens))`. Here is what it comes up with:

NN/B-NP IN/B-PP DT/B-NP NN/I-NP VBZ/B-VP RB/I-VP VBN/I-VP TO/I-VP VB/I-
VP DT/B-NP JJ/I-NP NN/I-NP

This is 100% correct.

5.5.3 Exercises

1. **Bigram chunker**: The bigram chunker scores about 90% accuracy. Study its errors and try to work out why it doesn’t get 100% accuracy.

2. **Trigram chunker**: Experiment with trigram chunking. Are you able to improve the performance any more?

3. (Advanced) **N-Gram Chunking Context**: An n-gram chunker can use information other than the current part-of-speech tag and the n-1 previous chunk tags. Investigate other models of the context, such as the n-1 previous part-of-speech tags, or some combination of previous chunk tags along with previous and following part-of-speech tags.

4. (Advanced) **Modularity**: Consider the way an n-gram tagger uses recent tags to inform its tagging choice. Now observe how a chunker may re-use this sequence information. For example, both tasks will make use of the information that nouns tend to follow adjectives (in English). It would appear that the same information is being maintained in two places. Is this likely to become a problem as the size of the rule sets grows? If so, speculate about any ways that this problem might be addressed.

5.6 Cascaded Chunkers

So far, our chunk structures have been relatively flat. Trees consist of tagged tokens, optionally grouped under a chunk node such as NP. However, it is possible to build chunk structures of arbitrary depth, simply by creating a multi-stage chunk grammar.
So far, our chunk grammars have consisted of a single stage: a chunk type followed by one or more patterns. However, chunk grammars can have two or more such stages. These stages are processed in the order that they appear. The patterns in later stages can refer to a mixture of part-of-speech tags and chunk types. Here is an example, which has patterns for noun phrases, prepositional phrases, verb phrases, and sentences.

```plaintext
>>> grammar = ""
... NP: {<DT|JJ|NN.*>+} # Chunk sequences of DT, JJ, NN
... PP: {<IN><NP>} # Chunk prepositions followed by NP
... VP: {<VB.*><NP|PP|S>+$} # Chunk rightmost verbs and arguments/adjuncts
... S: {<NP><VP>} # Chunk NP, VP
... ""
```

This is a four-stage chunk grammar, and can be used to create structures having a depth of at most four. The next step is to create the corresponding chunker in the usual way.

```plaintext
>>> cp = chunk.Regexp(grammar)
>>> input = chunk.tagstr2tree("""Mary/NN saw/VBD the/DT cat/NN
... sit/VB on/IN the/DT mat/NN""")
>>> print cp.parse(input)
(S: (NP: ('Mary', 'NN')) ('saw', 'VBD') (S: (NP: ('the', 'DT') ('cat', 'NN')) (VP: ('sit', 'VB') (PP: ('on', 'IN') (NP: ('the', 'DT') ('mat', 'NN'))))))
```

Unfortunately this result misses the VP headed by saw. It has other shortcomings too. Let's see what happens when we apply this chunker to a sentence having deeper nesting.

```plaintext
>>> input = chunk.tagstr2tree("""John/NNP thinks/VBZ Mary/NN saw/VBD
... the/DT cat/NN sit/VB on/IN the/DT mat/NN""")
>>> print cp.parse(input)
(S: (NP: ('John', 'NNP')) ('thinks', 'VBZ') (NP: ('Mary', 'NN')) ('saw', 'VBD') (S: (NP: ('the', 'DT') ('cat', 'NN')) (VP: ('sit', 'VB') (PP: ('on', 'IN') (NP: ('the', 'DT') ('mat', 'NN'))))))
```

The solution to these problems is to get the chunker to loop over its patterns: after trying all of them, it repeats the process. We add an optional second argument `loop` to specify the number of times the set of patterns should be run:

```plaintext
>>> cp = chunk.Regexp(grammar, loop=2)
>>> print cp.parse(input)
(S:
```
This cascading process enables us to create deep structures. However, creating and debugging a cascade is quite difficult, and there comes a point where it is more effective to do full parsing (see Chapter 7).

5.7 Conclusion

In this chapter we have explored efficient and robust methods that can identify linguistic structures in text. Using only part-of-speech information for words in the local context, a “chunker” can successfully identify simple structures such as noun phrases and verb groups. We have seen how chunking methods extend the same lightweight methods that were successful in tagging. The resulting structured information is useful in information extraction tasks and in the description of the syntactic environments of words. The latter will be invaluable as we move to full parsing.

There are a surprising number of ways to chunk a sentence using regular expressions. The patterns can add, shift and remove chunks in many ways, and the patterns can be sequentially ordered in many ways. One can use a small number of very complex rules, or a long sequence of much simpler rules. One can hand-craft a collection of rules, and one can write programs to analyze a chunked corpus to help in the development of such rules. The process is painstaking, but generates very compact chunkers that perform well and that transparently encode linguistic knowledge.

It is also possible to chunk a sentence using the techniques of n-gram tagging. Instead of assigning part-of-speech tags to words, we assign IOB tags to the part-of-speech tags. Bigram tagging turned out to be particularly effective, as it could be sensitive to the chunk tag on the previous word. This statistical approach requires far less effort than rule-based chunking, but creates large models and delivers few linguistic insights.

Like tagging, chunking cannot be done perfectly. For example, as pointed out by [Abney, 1996], we cannot correctly analyze the structure of the sentence I turned off the spectroroute without knowing the meaning of spectroroute; is it a kind of road or a type of device? Without knowing this, we cannot tell whether off is part of a prepositional phrase indicating direction (tagged B-PP), or whether off is part of the verb-particle construction turn off (tagged I-VP).

A recurring theme of this chapter has been diagnosis. The simplest kind is manual, when we inspect the tracing output of a chunker and observe some undesirable behavior that we would like to fix. Sometimes we discover cases where we cannot hope to get the correct answer because the part-of-speech tags are too impoverished and do not give us sufficient information about the lexical item. A second approach is to write utility programs to analyze the training data, such as counting the number of times a given part-of-speech tag occurs inside and outside an NP chunk. A third approach is to evaluate the system against some gold standard data to obtain an overall performance score. We can even use this to parameterize the system, specifying which chunk rules are used on a given run, and

February 1, 2007

Bird, Klein & Loper
tabulating performance for different parameter combinations. Careful use of these diagnostic methods permits us to optimize the performance of our system. We will see this theme emerge again later in chapters dealing with other topics in natural language processing.
